## Problem 5: Cancelling the k-th Last Order

### TASK

A restaurant keeps today's orders in a singly linked list, newest at the end. A customer cancels the order that is k-th from the end.

Implement `Node removeKthFromEnd(Node head, int k)` that removes that node in a single pass and returns the head. Use your own node class (for example `class Node { int data; Node next; }`); do not use `java.util.LinkedList` or other collections for the list itself.

### CONSTRAINTS

- 1 <= k <= length of list <= 10^4
- Single pass only

### EXAMPLES

**Sample 1**

```
orders = 10 -> 20 -> 30 -> 40 -> 50, k = 2

Expected Output: 10 -> 20 -> 30 -> 50
```

**Sample 2**

```
orders = 10 -> 20 -> 30 -> 40 -> 50, k = 5

Expected Output: 20 -> 30 -> 40 -> 50
```

### COMPLEXITY REQUIREMENTS

State the time and space complexity, and explain how the second sample (removing the head) is handled without a special case.

### HINT

> *Start a lead pointer k + 1 steps ahead of a trailing pointer that begins at a dummy node; move both until the lead pointer falls off the end.*

---
